SPACE-FILLING CURVES (SFC)

By: Amirhessam Tahmassebi Department of Scientific Computing Florida State University November 2015

OVERVIEW

- Introduction
- Type of Space-Filling Curves
 - 1. The Peano Space-Filling Curves
 - 2. The Hilbert Space-Filling Curves
 - 3. The Sierpinski Space-Filling Curves
 - 4. The Lebesgue Space-Filling Curves
- Applications of Space-Filling Curves

SURJECTIVE MAPPING:

The function is **surjective** (onto) if every element of the codomain is mapped to by at least one element of the domain.

Surjective map from A onto B : f(a) = b

If $f : A \rightarrow B$ then f is said to be surjective if $\forall b \in B, \exists a \in A, f(a) = b$

INJECTIVE MAPPING:

An **injective** function or injection or one-to-one function is a function that preserves distinctness: it never maps distinct elements of its domain to the same element of its codomain.

```
Injective map from A onto B : f(a) = b
```

If f: A \rightarrow B then f is said to be surjective if $\forall a, b \in A, f(a) = f(b) \rightarrow a = b$ or $\forall a, b \in A, a \neq b \rightarrow f(a) \neq f(b)$

BIJECTIVE MAPPING:

A function is **bijective** if it is both injective and surjective. A function is bijective if and only if every possible image is mapped to by exactly one argument.

If $f : A \rightarrow B$ then f is said to be bijective if For all $b \in B$, there's a unique $a \in A$ Such that f(a) = b

SPACE-FILLING CURVE (SFC) DEFINITION:

Intuitively, a continuous curve in 2 or 3 (or higher) dimensions can be thought of as the path of a continuously moving point.

HISTORY OF THE HILBERT CURVES:

- Hilbert Curves are named after the German mathematician David Hilbert. They were first described in 1891.
- A Hilbert curve is a continuous space-filing curve. They are also fractal and are self-similar; If you zoom in and look closely at a section of a higher-order curve, the pattern you see looks just the same as itself.
- An easy way to imagine creation of a Hilbert Curve is to envisage you have a long piece of string and want to lay this over a grid of squares on a table. Your goal is to drape the string over board so that the string passes through each square of the board only once.

THE HILBERT CURVE: GEOMETRIC GENERATION:

- If I can be mapped continuously on Ω , then after partitioning I into four congruent subintervals and Ω into four congruent subsquares, each subinterval can be mapped continuously onto one of the subsquares. This partitioning can be carried out ad infinitum.
- The subsquares must be arranged such that adjacent subintervals are mapped onto adjacent subsquares.
- Inclusion relationship: if an interval corresponds to a square, then its subintervals must correspond to the subsquares of that square.
- This process defines a mapping $f_h(I)$, called the Hilbert space-filling curve.

THE HILBERT CURVE: GEOMETRIC GENERATION:

APPLICATION: 1D INTO 2D:

- We find that if we convert the distance (d) shown on the tape-measure to a pair of (x,y) coordinates on the grid, then we find that other marks on the tape measure (close to d) have (x,y) coordinates that are very close.
- We have created a useful mapping function between one-dimension and two-dimensions that does a good job of preserving locality.

• To the right you can see the rainbow painted, using a Hilbert Curve. Colors that are close to each other on the spectrum have similar (x,y)coordinates.

HIGHER DIMENSIONS:

- The characteristics of Hilbert Curves can be extended to more than two dimensions. A 1D line can be wrapped up in as many dimensions as you can imagine.
- A rendering of a curve in 3D can is shown on the left.
 In this shape, points on the line numerically close
 to one another are also close in 3D space.
- It's easy to see how this can be extended into higher dimensions.
