Lab X: Romberg integration

Due on Monday March 21th, noon.
By email to beerli@fsu.edu [ use Subject: ISC5315: lab X]

1. Familiarize yourself with the Richard’s extrapolation and Romberg integration, use the the material on the next page

2. Write a program to take any polynomial up to degree=7 and a given accuracy (for example up to 8 digits) calculate the integral of that polynomial using Romberg integration with the trapezoidal rule \(R(n,0)\) and Simpson’s rule \(R(n,1)\). Use either C++ or Java. Assume that the user either gives the polynomial by hand or then has several polynomials in a file (one per line). Ideally your program will work with and without command-line options.

3. Your program should print out the original formula, the accuracy, the integration result.

4. Allow for an option in your program so that a user can see the convergence process by showing the results and the improvement.

5. Write a report that shows how you implemented the program, in particular I will look for section that uses pseudocode to explain the structure of your program.

6. Send report (PDF file) and the program as tar.gz archive.
**Romberg Integration**

- **Trapezoid formula**
  - with \( n \) subintervals gives error \( \sim 1/n^2 \)
  - I repeat the calculation with \( 2n \) subintervals
  - Can I combine to get a better estimate?

- **Error in trapezoidal**
  \[
  E = \frac{(b-a)^3}{12n^2} \max_{x\in[a,b]} f''(x)
  \]
  if I assume that this is independent of \( n \)

  \[
  E = \frac{C}{n^2}
  \]

**Romberg Integration**

- If we assume that “C” is roughly constant
  - \( I_{\text{true}} \) = true value of the integral
  - \( I_n \) = numerical approximation using “\( n \)” steps

- We have
  \[
  I_{\text{true}} = I_n + E(n)
  \]

  \[
  E(n) \approx \frac{C}{n^2} = I_{\text{true}} - I_n
  \]

  \[
  E(2n) \approx \frac{C}{4n^2} = I_{\text{true}} - I_{2n}
  \]

\[
I_{\text{true, est}} = I_{2n} + \frac{I_{2n} - I_n}{3}
\]

**Romberg Integration**

- **Example**
  - vertical distance covered by a rocket between 8 and 30 s.

  \[
  x = \int_8^{30} \left[ 2000 \ln \left( \frac{140000}{140000 - 2100t} \right) - 9.8t \right] dt
  \]

  Exact Answer: 11061 m

<table>
<thead>
<tr>
<th>( n )</th>
<th>Value</th>
<th>( E_i )</th>
<th>RelErr</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>11168</td>
<td>907</td>
<td>7.296</td>
</tr>
<tr>
<td>2</td>
<td>11266</td>
<td>205</td>
<td>1.854</td>
</tr>
<tr>
<td>3</td>
<td>11153</td>
<td>91.4</td>
<td>0.8265</td>
</tr>
<tr>
<td>4</td>
<td>11113</td>
<td>51.5</td>
<td>0.4655</td>
</tr>
<tr>
<td>5</td>
<td>11094</td>
<td>33.0</td>
<td>0.2981</td>
</tr>
<tr>

<td>11078</td>
<td>16.8</td>
<td>0.1521</td>
</tr>
<tr>
<td>8</td>
<td>11074</td>
<td>12.9</td>
<td>0.1165</td>
</tr>
</tbody>
</table>

**Romberg Integration**

- Use Richardson extrapolation

  \[
  I_2 = 11266
  \]

  \[
  I_4 = 11113
  \]

  \[
  I_{\text{true, est}} = I_4 + \frac{I_4 - I_2}{3} = 11062
  \]

  If you already have done \( I_4 \), then very little extra work
  - \( I_2 \) uses a subset of the same function evaluations

**Romberg Integration**

**Multistep trapezoidal rule**
Romberg Integration

- Usually much better estimates

<table>
<thead>
<tr>
<th>n</th>
<th>Trapezoidal Rule</th>
<th>e, for Trapezoidal Rule</th>
<th>Richardson's Extrapolation</th>
<th>e, for Richardson's Extrapolation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>11868</td>
<td>7.296</td>
<td>~</td>
<td>~</td>
</tr>
<tr>
<td>2</td>
<td>11266</td>
<td>1.854</td>
<td>11065</td>
<td>0.03616</td>
</tr>
<tr>

<td>0.4655</td>
<td>11062</td>
<td>0.009041</td>
</tr>
<tr>
<td>8</td>
<td>11074</td>
<td>0.1165</td>
<td>11061</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

Error Estimate

- It can be shown that
  \[ E = \frac{C_1}{n^2} + \frac{C_2}{n^4} + \frac{C_3}{n^6} + \ldots \]
- For the scheme
  \[ I_{true, est} = I_{2n} + \frac{I_{2n} - I_n}{3} \]
- The leading error is \( O(1/n^4) \)
  - like Simpson’s
  - In Numerical Recipes, this is how Simpson’s is implemented

Successive Refinement

- General Expression for Romberg Integration
  \[ I_{2n}^{(k)} = \frac{4^k I_{2n}^{(k-1)} - I_n^{(k-1)}}{4^{k-1} - 1} \quad k \geq 2 \]
  - index \( k \) represents order of extrapolation
  - \( I_n^{(1)} \) represents regular trapezoidal with \( n \) segments
  - \( k = 2 \) represents values using the true estimate as \( O(h^2) \)
  - \( I_n^{(k)} \) has an error of order \( 1/h^{2k} \)

In our particular example

Romberg's method
From Wikipedia, the free encyclopedia

In numerical analysis, Romberg's Method (Romberg 1955) generates a triangular array consisting of numerical estimates of the definite integral

$$\int_a^b f(x) \, dx$$

by applying Richardson extrapolation (Richardson 1910) repeatedly on the trapezium rule or the rectangle rule (midpoint rule). Romberg's method is a Newton–Cotes formula -- it evaluates the integrand at equally-spaced points. The integrand must have continuous derivatives, though fairly good results may be obtained if only a few derivatives exist. If it is possible to evaluate the integrand at unequally-spaced points, then other methods such as Gaussian quadrature and Clenshaw–Curtis quadrature are generally more accurate.

Method

The method can be defined inductively

$$R(0, 0) = \frac{1}{2} (b - a)(f(a) + f(b))$$

$$R(n, 0) = \frac{1}{2} R(n - 1, 0) + h_n \sum_{k=1}^{2^{n-1}} f(a + (2k - 1)h_n)$$

$$R(n, m) = R(n, m - 1) + \frac{1}{4^m - 1} (R(n, m - 1) - R(n - 1, m - 1))$$

or

$$R(n, m) = \frac{1}{4^m - 1} (4^m R(n, m - 1) - R(n - 1, m - 1))$$

where

$$n \geq 1$$

$$m \geq 1$$
In big O notation, the error for $R(n, m)$ is (Mysovskikh 2002):

$$O\left(h_n^{2m+2}\right).$$

The zeroeth extrapolation, $R(n, 0)$, is equivalent to the trapezoidal rule with $2^n + 1$ points; the first extrapolation, $R(n, 1)$, is equivalent to Simpson's rule with $2^n + 1$ points. The second extrapolation, $R(n, 2)$, is equivalent to Boole's rule with $2^n + 1$ points. Further extrapolations differ from Newton Cote's Formulas. In particular further Romberg extrapolations expand on Boole's rule in very slight ways, modifying weights into ratios similar as in Boole's rule. In contrast, further Newton Cotes methods produce increasingly differing weights, eventually leading to large positive and negative weights. This is indicative of how large degree interpolating polynomial Newton Cotes methods fail to converge for many integrals, while Romberg integration is more stable.

When function evaluations are expensive, it may be preferable to replace the polynomial interpolation of Richardson with the rational interpolation proposed by Bulirsch & Stoer (1967).

**Example**

As an example, the Gaussian function is integrated from 0 to 1, i.e. the error function $\text{erf}(1) \approx 0.842700792949715$. The triangular array is calculated row by row and calculation is terminated if the two last entries in the last row differ less than $10^{-8}$.

<td>0.84270079</td>
<td>0.84270079</td>
<td>0.84270079</td>
<td></td>
</tr>
<tr>
<td>0.84243051</td>
<td>0.84270093</td>
<td>0.84270079</td>
<td>0.84270079</td>
<td>0.84270079</td>
<td>0.84270079</td>
<td></td>
</tr>
</tbody>
</table>

The result in the lower right corner of the triangular array is accurate to the digits shown. It is remarkable that this result is derived from the less accurate approximations obtained by the trapezium rule in the first column of the triangular array.

**Implementation**

Here is an example of a computer implementation of the Romberg method (In the C programming language), it needs one vector and one variable; it also needs a sub-routine trapeze:

```c
#include <stdio.h>
#include <stdlib.h>
#include <math.h>
#define MAX 6

int main()
{
    double s[MAX];
    int i,k;
```
double var;
for (i = 1; i < MAX; i++)
    s[i] = 1;
for (k=1; k < MAX; k++)
{
    for (i=1; i <= k; i++)
    {
        if (i==1)
        {
            var = s[i];
            s[i] = Trap(0, 1, pow(2, k-1)); // sub-routine tra,
            // integrated from /* pow() is the nu.
        }
    }
    else
    {
        s[k]= ( pow(4 , i-1)*s[i-1]-var )/(pow(4, i-1) - 1);
    }
    var = s[i];
    s[i] = s[k];
}
for (i=1; i <=k; i++)
    printf("  \%f  ", s[i]);
    printf("\n");
return 0;
}
